

Lecture

\* HW will be graded and returned soon.

\* Assignment 2 will be posted soon.

We are finishing Chs. 4, 5 and will start Ch. 6 content soon.

Last time: Prove by induction on the Structure of Lists

$\forall L. P(L)$   
 $\uparrow$  List       $\uparrow$  property

① Prove base case with List  
 (empty or non-empty)  
 $P([])$

② Inductive ~~base~~ case:

How can we prove for all non empty lists?

$\forall x. \forall xs. P(xs) \Rightarrow$   
 $\begin{matrix} \downarrow & \downarrow \\ \text{element} & \text{List} \end{matrix} \quad P(x:xs)$

So we assume it works for all since we tacked the ~~non-empty~~ element at the beginning.

# Haskell Datatypes

Lots of types of polymorphic type:

$[Int]$   $[Bool]$   $[ [Int] ]$  etc.

We can use this in type declaration of functions, such as:  $length : [a] \rightarrow Int$ .

$map : (a \rightarrow b) \rightarrow [a] \rightarrow [b]$

This is valid for any uniform instantiation of type variables.

List types:

- Empty  $[]$
- Non empty  $x : xs$   
 $\downarrow \quad \downarrow$   
 $a \quad [a]$

} This is a recursive definition b/c the non-empty list contains itself.

Variant types (sum):

Can have different things in it.

Define them by the data keyword!!

Example: Data type for natural numbers:  $(0, 1, 2, \dots)$

$data\ Nat = zero \mid Succ\ Nat$   
 $\downarrow \quad \quad \downarrow \quad \quad \downarrow$   
name of data type type constructors type argument (to succ)

Just as you have reg. functions, you can do similar things w/ Haskell:

0 ~~~~~ represented by ~~~~~ ~~zero~~ zero  
1 ~~~~~ represented by ~~~~~  $Succ\ zero : Nat$  ②

Succ fails b/c Succ 1 Int not Nat.

Succ :: Nat  $\rightarrow$  Nat.

Say you have a list and want to add One to them:

map Succ [zero, Succ zero]  
[Succ zero, Succ (Succ zero)]

What if you wanted to add ~~Int~~<sup>Nat</sup> together?

add Nat :: Nat  $\rightarrow$  Nat

add Nat zero ~ 2 = ~ 2

add Nat (Succ ~ 1) ~ 2 = Succ (add Nat ~ 1 ~ 2)

What about mathematical induction?

Use to prove for  $\forall n :: \text{Nat}. P(n)$ ,

①  $P(\text{zero})$

②  $\forall n :: \text{Nat}. P(n) \Rightarrow P(\text{Succ } n)$

Another use: Representing shapes !!

data shape = Circle Double

          | Square Double

          | Rectangle Double Double

          | EqTri Double (equilateral  $\Delta$ )

What function can calculate area of a shape?

area :: Shape  $\rightarrow$  Double

area (Circle r) =  $\pi * r * r$

area (Square n) =  $n * n$

area (Rectangle m n) =  $m * n$

area (EqTri n) =  $0.5 * n * h$  where  $h = 0.5 * n * (\sqrt{3})$  ③

$m \cap n \subseteq M$ .  $C_{m \cap n} = M$ .  $S_{m \cap n}$

What if we added Pentagon?

We have to add ~~it~~ it to type declaration  
and to every function! Otherwise it won't  
be recognized.

Another type class: Show

It's a class of types  $\{ \text{show} \dots a \rightarrow \text{String} \}$   
This function is used to produce the String.

Default  $\rightarrow$  autogenerates  $\text{show} : \text{Shape} \rightarrow \text{String}$ .

OR you can promote your own orientation:

$\text{Show} (\text{Circle } r) \dots$

$(\text{Circle } 1.0) == (\text{Circle } (2.0 - 1.0))$  } ~~Predefined~~  
 } ~~show~~  
 } ~~autogenerated~~  
 } ~~for all types~~  
 } Needs to  
 } type check!

Instance of Shape where:

~~$(\text{Circle } r_1) = (\text{Circle } r_2) \iff r_1 = r_2$~~   
 ~~$(\text{Rectangle } r_1) = (\text{Circle } r_2) \iff \text{False}$~~

Auto generating  $==$  will fail if there is a  
function type as adjustment to a type constructor.

Using a List example (to redefine number type):

$\text{data MyList } a = \text{MyEmpty} \mid \text{MyCons } a (\text{MyList } a)$

$\text{myMap} :: (a \rightarrow b) \rightarrow \text{MyList } a \rightarrow \text{MyList } b$

}  $\text{MyList } a$  is  
} polymorphic.  
It's also recursive  
b/c defined by  
itself.

My Map f ~~My~~ Empty = My Empty

myMap f (My Cons x xs) = My Cons (f x)  
(My Map + xs)

a

myList 'a'

What if we wanted a binary tree?

data Tree a = Leaf a  
= Node (Tree a) (Tree a)

=> Node (Leaf 1)  
(Node (Leaf 2) (Leaf 3))  
: Tree Int.

treeMap : (a -> b) -> (Tree a) -> (Tree b)  
treeMap f (Leaf x) = Leaf (f x)

What if you wanted to flip?

treeFlip : Tree a -> Tree a

treeFlip (Leaf x) = Leaf x } so leave it alone!

treeFlip (Node t1 t2) = ~~Node t2 t1~~ (treeFlip t2)  
(treeFlip t1)

Here, you can't just flip the order.

What about a fold? Iterate across data structure:

$\text{treeFold} : (a \rightarrow b) \rightarrow (b \rightarrow b \rightarrow b) \rightarrow (\text{Tree } a) \rightarrow b$

$\text{treeFold } f_{\text{Leaf}} \ f_{\text{Node}} (\text{Leaf } x) = f_{\text{Leaf}} x$

$\text{treeFold } f_{\text{Leaf}} \ f_{\text{Node}} (\text{Node } t_1 \ t_2)$

$= f_{\text{Node}} (\text{treeFold } f_{\text{Leaf}} \ f_{\text{Node}} \ t_1) (\text{treeFold } f_{\text{Leaf}} \ f_{\text{Node}} \ t_2)$

$\text{Node} (\text{Leaf } 1) (\text{Node} (\text{Leaf } 2) (\text{Leaf } 3))$

~~turns into~~ Turns into:

$f_{\text{Node}} (f_{\text{Leaf}} 1) (f_{\text{Node}} (f_{\text{Leaf}} 2) (f_{\text{Leaf}} 3))$

Could implement as:

$\text{sumTree} : \text{Tree } \text{Int} \rightarrow \text{Int}$

$\text{sumTree } t = \text{treeFold } (\text{Int} \rightarrow \text{Int}) (t) t$
